# Groundwater data management

Arnaud Sterckx, IGRAC

 After data is collected in the field (or in the lab), it needs to be properly managed.

Groundwater data management is the whole process of using groundwater data after their collection. It encompasses quality assurance and quality control (QA/QC) of those data, the storage of those data in archives and databases, sharing/providing access to data, analysis and interpretation of the data, and finally the dissemination of resulting groundwater information.

SADC-GMI, IGRAC, IGS (2019) SADC Framework for Groundwater Data Collection and Data Management. SADC-GMI report: Bloemfontein, South Africa.

Online Course on Groundwater Management in African Lake and River Basin Organizations

RESOURCES IN TRANSBOUNDARY AQUIFERS

# **Frequent shortcomings**

# Budget

- Insufficient staff
- Insufficient equipment (e.g. piezometers, sampling sets, transport, computers, lab analyses, IT)

# Monitoring objectives and strategy

- Few official groundwater data collection plans with dedicated budgets and numbered objectives
- Absence of clear groundwater monitoring purposes

*GW-MATE, 2006* 

Effective groundwater monitoring is characterized by two key requirements:

- it should be driven by a specific objective—monitoring for its own sake often leads to inefficient use of manpower and budgets
- the data collected should be systematically stored for future use—there are far too many cases of monitoring data being 'lost along the way'.
- Related issues: access to monitoring boreholes, irregular sampling, etc.

https://www.un-igrac.org/special-project/gw-mate

## Interpretation of groundwater data

- Lack of interpretation of groundwater data: No interpretation because no data? Or no data because no interpretation?
- Lack of training
- Lack of software programs

# QA/QC procedures

- The data collected are sometimes (often?) of poor quality
- Lack of protocols and guidelines (for monitoring, siting, drilling and testing, for lab analyses, data check)
- Lack of field forms/templates
- Lack of data interpretation

## Data storage and sharing

- Few countries rely on relational databases and software programs. Spreadsheets and hardcopies are still frequently used.
- Data are stored in different locations
- Lack of reliable data backup strategies

*GW-MATE, 2006* 

Effective groundwater monitoring is characterized by two key requirements:

- it should be driven by a specific objective—monitoring for its own sake often leads to inefficient use of manpower and budgets
- the data collected should be systematically stored for future use—there are far too many cases of monitoring data being 'lost along the way'.
- Barrier to data sharing

Online Course on Groundwater Management in African Lake and River Basin Organizations

#### 3.4.2. Reported issues

The issues reported by the interviewees during the country visits are listed below. They are also summarized in Table 8, with the countries where they have been reported. Again, this table may not be exhaustive or accurate, but it gives a general idea of the main challenges that need to be addressed in the Member States.

#### > Issues related to data collection

- Insufficient number of BH being monitored: There are insufficient monitoring boreholes to fulfil the monitoring objectives; e.g. they don't cover the entire territory of the Member States or the monitoring network is not dense enough to provide significant insight on groundwater resources.
- Issues in the design of monitoring network or monitoring boreholes: The monitoring
  network is not efficient because the monitoring boreholes have not been located in the
  right places, they don't always tap into the right aquifers, or information on the
  construction of the boreholes is missing, etc.
- Damaged observation boreholes or observation boreholes turned into production wells: Monitoring boreholes are not repaired when damaged or have been equipped with pumps. This reduces the size of the monitoring network.
- · Vandalism: Monitoring boreholes and infrastructure are damaged by locals.
- No data or incomplete data from private groundwater users: In many Member States, private groundwater users must report to the authority in order to get a license, but they don't.
- Gaps in monitoring data series: The monitoring boreholes are not monitored as often as desired; the frequency of monitoring is variable.
- Issues with data quality and data quality check: The quality of the data collected is poor or is not checked.
- Problems of data loggers maintenance: Data loggers collect data automatically but they
  need to be visited regularly to be recharged and to save the data. If this is not done on a
  regular basis this may result in loss of data (data gaps).
- Need for automatic data loggers: Collecting data with data loggers requires less efforts than collecting data manually. Or for the same effort, they allow collecting more data than manually.
- > Issues related to data storage
- No centralized database / use of spreadsheets
- Use of hardcopies
- No national coding system of BH or issues with BH numbering
- Use of different coordinate systems
- No backup system
- > Issues related to data sharing
- Data sharing can be difficult

# igrae

- Lack of interpretation, resulting in ad-hoc interventions and lack of interest (= lack of budget) from decision makers.
- > Issues related to all components of data collection and data management
- Limited resources (e.g. budget, staff, equipment)
- Logistics/organizational issues
- No official monitoring plans
- No clear objectives of groundwater monitoring
- Lack of training

## Responsibilities

- In most countries, groundwater monitoring and the collection of borehole data is in the hands of a public authority, e.g. ministry of water, water authority, geological survey, etc.
- In some countries, water management is decentralized (e.g. Mozambique). Groundwater data might be collected and managed by subnational authorities.
- Additional data might be held by other ministries or departments (e.g. environment), water companies, universities, NGOs, private companies, etc.
- → It is sometimes challenging to identify who collects and manages groundwater data

# What data are available?

- In low-income countries, it is often the case that groundwater monitoring programs are insufficient and borehole licensing is not effective.
- → Identify what data are actually being collected.
- In case of monitoring:
- groundwater level?
- groundwater quality? If yes, what parameters
- groundwater abstraction?
- How many data point are monitored? What is the frequency of monitoring?
- In case of borehole data:
- What data are collected? Is the inventory of boreholes up-to-date?

# What is the quality of the data?

- When data are available, it happens that they are of poor/dubious quality.
- What are the protocols followed in the field or in the lab?
- What are the QA/QC procedures to ensure a good quality of the data?
- Are metadata stored with the data?

# How are data shared?

- What are the conditions under which data are shared?
- Is there a data sharing platform?
- Is it necessary to request the data?
- Is it necessary to pay a fee?
- What is the waiting time before receiving the data?
- Is there a data management strategy?

Bureau of Meteorology, 2017. Good practice guidelines for water data management policy: World Water Data Initiative. Bureau of Meteorology, Melbourne

! There is often a gap between policy documents and practice

! The situation can change rapidly, depending on e.g. political changes, budgets, etc

And many more!

### Recommendation

- L/RBOs should have insight on groundwater data collection and management in the riparian states.
- There is a value in transboundary cooperation for capacity building in groundwater assessment and management, e.g. for attracting funding, sharing of experiences and good practices, economies of scale. See for instance:

<u>https://sadc-gmi.org/</u>

L/RBOs can be instrumental in fostering such cooperation between countries.

# Thank you for your attention
